ABSTRACT

Man, since the earliest times, established two taboos: the taboo of incest and the taboo of killing, which shows how much importance has always been attached to aggressive behavior and destruction. When we talk about aggression and its motivation and consequences, it should be emphasized that it is the subject of interest primarily in forensics, but lately it has also been investigated in the framework of neuropsychological and neurobiological works. Unlike benign aggression, which has a biologically adaptive function and is characteristic of both humans and animals, malignant aggression can be "wrapped" in various forms and forms of violent behavior with the aim of satisfying the aggressor and characteristically occurs only in humans. The paper discusses the very concept of aggression and its indicators on two personality inventories, which have recently been more intensively used in psychological psychodiagnostic work: PAI and MCMI III.

Keywords: aggressiveness, PAI, MCMI III.
